\begin{abstract}
In 1990, Bock and Loebell found that passives (e.g., \textit{The 747 was radioed by the airport's control tower}) can be primed by intransitive locatives (e.g., \textit{The 747 was landing by the airport's control tower}). This finding is often taken as strong evidence that structural priming occurs on the basis of a syntactic phrase structure that abstracts across lexical content, including prepositions, and is uninfluenced by the semantic roles of the arguments. However, all of the intransitive locative primes in Bock and Loebell contained the preposition \textit{by} (by-locatives), just like the passive targets. Therefore, the locative-to-passive priming may have been due to the adjunct headed by \textit{by}, rather than being a result of purely abstract syntax. The present experiment investigates this possibility. We find that passives and intransitive locatives are equivalent primes, but intransitive locatives with other prepositions (e.g., \textit{The 747 has landed near the airport control tower}) do not prime passives. We conclude that a shared abstract, content-less tree structure is not sufficient for passive priming to occur. We then review the prior results that have been offered in favor of abstract tree priming, and note the range of evidence can be considerably narrowed—and possibly eliminated—once effects of animacy, semantic event structure, shared morphology, information structure, and rhythm are taken into account.
\end{abstract}

1. Introduction

When we speak to one another, we must take our ideas (our messages), convert them into words, and combine those words to form utterances. It is easy to conceive of the lexical and combinatorial processes as separable, and many early linguistic and psycholinguistic models argued that words and syntax were generated by wholly distinct systems (Chomsky, 1994; Frazier & Fodor, 1978). At the same time, we have long recognized that lexical and syntactic representations are often intimately related, with each representation constraining the other (Chomsky, 1965; Culicover, 1999; Fillmore, 1968; Jackendoff, 1975; Lakoff, 1970; Levelt, 1993; MacDonald, Pearlmutter, & Seidenberg, 1994; Trueswell, Tanenhaus, & Garnsey, 1994).

One powerful tool used to explore the relationship between word choice and syntactic structure has been \textit{structural priming}, which describes the tendency for speakers to re-use previously encountered sentence structures (Bock, 1986; for meta-analysis and reviews, see Branigan, 2007; Branigan & Pickering, 2017; Ferreira & Bock, 2006; Mahowald, James, Futrell, & Gibson, 2016; Pickering & Ferreira, 2008; Tooley & Traxler, 2010; Traxler & Tooley, 2012). For instance, Bock (1986) showed that speakers were more likely to describe a picture with a to-dative (e.g., \textit{The man is reading a story to the boy}) after using a different to-dative (e.g., \textit{A rock star sold some cocaine to an undercover agent}) than after using a double-object dative (\textit{A rock star sold an undercover agent some cocaine}). Within the structural priming literature, there is evidence that structural priming is increased when the prime and target sentences share a content word (i.e., \textit{the lexical boost}; Cleland & Pickering, 2003; Pickering & Branigan, 1998). But we know that structural priming occurs even when prime and target do not overlap in content or function words (Bock, 1986, 1989).

Critically, structural priming has been argued to only require shared abstract syntax, occurring even in the absence of shared argument types (\textit{semantic roles}), shared discourse-related properties, or shared words (Bock & Loebell, 1990; Bock, 1986, 1989). In other words, structural priming has been thought to reflect the priming of abstract, content-less tree structures (for discussion, see Branigan, 2007; Branigan & Pickering, 2017; Branigan, Pickering, Liversedge, Stewart, & Urbach, 1995; Chang, Dell, & Bock, 2006). For this reason, the effect is often referred to as \textit{syntactic priming}, rather than the more neutral term, \textit{structural priming}, that we adopt here.

A key piece of evidence that has been used to argue in favor of fully abstract syntactic priming is, on closer examination, ambiguous. Bock and Loebell (1990, Exp. 2) found that participants produced as many passive sentences following intransitive locative sentences (\textit{The 747 was...})
landing by the airport’s control tower) as they did after other passives (The 747 was alerted by the airport’s control tower). While passives and intransitive locatives appear to share the same abstract syntax (following, e.g., Emonds, 1976; though see Section 4.1 for alternative analyses), their semantics is clearly distinct. In a passive sentence like The 747 was alerted by the airport’s control tower, the control tower is the actor of the action and the 747 is the undergoer of the action; in the intransitive locative, The 747 was landing by the airport’s control tower, the 747 is the argument that is acting and the control tower is a location. Thus, this data point seems to demonstrate that abstract phrase structures can be argued that is acting and the control tower is a location. Thus, this locative, alerted by the airport’s control tower

The 747 was

landing by the airport’s control tower, the 747 is the argument that is acting and the control tower is a location. Thus, this data point seems to demonstrate that abstract phrase structures can be primed. This study, however, contains a lexical confound: All of the intransitive locative primes contained the preposition by and the auxiliary be, just like the passive targets, while none of the actives did. Therefore, the locative-to-passive priming that was found may have been due in part or in whole, to the shared lexical material. If locative-to-passive priming requires lexical overlap, it would remove the strongest evidence we have that priming can occur on the basis of fully abstract syntactic representations (for discussion, see, e.g., Desmet & Declerq, 2006; Ferreira, 2003; Goldberg, 2006, ch. 6.10; Hare & Goldberg, 1999; Hartsuiker, Kolk, & Huiskamp, 1999, fn. 3). Bock and Loebell (1990) acknowledged this concern. Their conclusion that the locus of this priming was purely syntactic rested on evidence from another construction and the assumption that all argument structure alterations are primed in the same way.

Specifically, Bock (1989) had shown previously that for-datives (e.g., The secretary is baking a cake for her boss) are just as good at eliciting to-dative target descriptions (e.g., The girl is handing the paintbrush to the man on the ladder) as other to-dative primes (e.g., The secretary is taking a cake to her boss; see also Chang, Bock, & Goldberg, 2003; Ziegler & Snedeker, 2018). For-to-dative priming, however, is also ambiguous. Critically, the two dative constructions have common semantic properties which could be responsible for the priming. Specifically, the semantic event structures ascribed to to-datives and for-datives are closely related (e.g., Jackendoff, 1972, 1983; Lakoff & Johnson, 1980), and critically, are distinct from the semantic event structure of double-object datives, which is the same regardless of whether the sentences can be paraphrased using to or for (Goldberg, 2002; Green, 1974). At the time Bock and Loebell (1990) presented their findings, there was no evidence that semantic event structure could be primed. Now, however, there is ample evidence for this form of priming in dative and closely related constructions (see, e.g., Cai, Pickering, & Branigan, 2012; Chang et al., 2003; Cho-Reyes, Mack, & Thompson, 2016; Hare & Goldberg, 1999; Köhne, Pickering, & Branigan, 2014; Pappert & Pechmann, 2014; Salamoura & Williams, 2007; Yi & Koenig, 2016; Ziegler & Snedeker, 2018; Ziegler, Snedeker, & Wittenberg, 2018).

For example, Chang et al. (2003) found that location-theme locative sentences (e.g., The maid rubbed the table with polish) led to more location-theme responses (e.g., The farmer heaped the wagon with straw), which share a semantic event structure, as compared to theme-location locatives (e.g., The maid rubbed polish onto the table), which have a different semantic event structure (see also Yi & Koenig, 2016; Ziegler & Snedeker, 2018; for evidence of locative priming in Brazilian Portuguese, see Ziegler, Morato, & Snedeker, in press). Critically, this priming occurred independently of syntax and animacy, which were the same across prime types. Similarly, Ziegler et al. (2018) showed that compositional dative primes (e.g., The culprit gives the attorney a check) yielded greater priming on compositional dative targets (e.g., The boy gives the cowboy a rope) than did either idiomatic dative primes (e.g., The audience gives the performer his due) or light verb dative primes (e.g., The boy gives the girl a hug; see also Griffin & Weinstein-Tull, 2003, for a semantic boost in clausal complement constructions). The compositional dative primes and targets were matched on syntactic phrase structure, semantic event structure, and syntax-animacy mappings, while the idiomatic and light verb dative primes had only the same syntactic phrase structure and syntax-animacy mappings, thus implicating semantic event structure as the locus of the difference in priming (for further discussion of the involvement of event representation in priming, see Ziegler, 2019; Ziegler et al., 2018).

Thus, for-to-to-dative priming cannot distinguish between priming on the basis of syntax and priming based on semantic event structure, or some combination of these factors. This observation makes it all the more important to determine whether the locative-to-passive priming reported by Bock and Loebell (1990) was truly the result of priming a fully abstract phrase structure, or whether it depended critically on the shared lexical content (the use of by and the same auxiliary, be). Passive-to-passive priming is a well-replicated phenomenon (see Mahowald et al., 2016). However, to the best of our knowledge, no study rules out the lexical hypothesis (including, e.g., Messenger & Branigan, 2011), a point we will elaborate on in the discussion.

The experiment reported in this paper therefore has two primary goals. First, we aimed to replicate Bock and Loebell (1990, Exp. 2) original finding with a much larger sample of participants and updated statistical tools, as the study has been a theoretical lynchpin in priming research for almost 30 years. Save for the confounding inclusion of by and be, the fact that the intransitive locative condition primed passives has stood as the strongest evidence in favor of fully abstract syntax. And yet we are unaware of any published replications. In addition, and more relevantly for the current discussion, we set out to determine whether the locative-to-passive priming in Bock and Loebell (1990) was based, in whole or in part, on shared abstract syntax devoid of lexical content. Specifically, we ask whether passives are primed by intransitive locatives that do not contain the preposition by or the same auxiliary. Therefore, we added a fourth condition to Bock and Loebell (1990) design: intransitive locatives that did not contain by or be (e.g., The 747 has landed near the airport control tower). If we find that these sentences are equally good primes for passive sentences as intransitive by-locatives, it would provide strong evidence in favor of fully abstract syntax.

In the discussion, we situate the current findings in a broader context by reviewing a range of prior work that has argued in favor of abstract syntactic priming. While we do not and cannot rule out the possibility that abstract syntactic priming exists, we suggest that the majority of previous results allow the possibility that the effects reported required shared lexical content, shared semantic event structure, shared information structure, shared prosody. As discussed there, it could be that different factors are more or less relevant for different types of constructions.

2. Methods

2.1. Participants

300 native English speakers recruited from Amazon Mechanical Turk participated (166 female, 129 male, 4 trans, 1 unreported; mean age = 36, SD = 11, range = 18–73). All participants provided written consent (in accordance with the guidelines of the Committee on the Use of Human Subjects at Harvard University) prior to participating and received $4.50 in compensation.

1 Likewise, Messenger and Branigan (2012) found that children (ages 3–4) and adults produced more passives after passives that were quite different semantically. In particular, they found that children were more likely to produce undergoer-agent passives (e.g., A girl is being hit by a sheep) after experiencer-theme passives (e.g., A girl is being shocked by a sheep) than after actives. Putting aside the possibility that in both cases causer and theme arguments might be involved, all of the primes again included the word by.

2 Alternatively, the for-to-to-dative priming could be the result of animacy priming. We know that the order of animate and inanimate arguments can be primed (Bock, Loebell, & Morey, 1992; Gámez & Vasilyeva, 2015; Ziegler & Snedeker, 2018). Such priming could also ensure that to-datives would prime for-datives over the alternative double-object option.
Fig. 1. Constituent structure for (a) active transitives and (b) passives or intransitive locatives.

2.2. Materials

The study consisted of 32 critical trials interspersed with 68 filler trials, for a total of 100 trials. All trials included a sequence of one prime sentence, presented as text to be read out loud, followed by a target picture, described below. The sentence primes were 32 sets of transitive sentences in each of four priming conditions: full passive (Passive; e.g., The 747 was radioed by the airport control tower), active transitive (Active; e.g., The 747 radioed the airport control tower), intransitive locative with a by-phrasal (By-locative; e.g., The 747 was landing by the airport control tower), and intransitive locative with a non-by-phrase (Non-locative; e.g., The 747 has landed near the airport control tower). Some of the intransitive verbs came from the original Bock and Loebell (1990) stimuli; the remainder were chosen with the requirement that they made sense and were grammatical in the intransitive locative construction (with by and at least one other preposition). We represent the structure of active transitive sentences in Fig. 1a, and the structure of the other sentence types, including passive, intransitive-by-locative, and intransitive non-locative sentences, in Fig. 1b (the possibility that the representation in Fig. 1b is invalid is addressed in Section 4.1). (For a full list of all prime sentences, see Appendix A.)

In the Active primes, an agent of the action appeared in the subject NP (e.g., The 747), the verb was expressed in past tense in the active voice (e.g., radioed), and a direct object NP contained an undergoer argument (e.g., airport control tower). In the corresponding Passive primes, the undergoer appeared in the subject NP (e.g., The 747), the verbal predicate included the auxiliary be and a past participle (e.g., was radioed), and the agent of the action appeared in a PP headed by the preposition by (e.g., by the airport control tower). In the By-locative primes, the agent of the action appeared in the subject NP (e.g., The 747), the verbal predicate included the auxiliary be and a progressive intransitive verb (e.g., was landing), and the PP contained the locative preposition by followed by the object NP (e.g., by the airport control tower). The semantic role of the oblique noun (e.g., airport control tower) was that of location. Finally, in the Non-by-locative primes, the agent of the action appeared in the subject NP (e.g., The 747), the verbal predicate included the auxiliary have and a past participle (e.g., has landed), and the PP was identical to its By-locative counterpart except for the presence of a different preposition (e.g., near the airport control tower vs. by the airport control tower).3

We used he in our By-locatives in order to replicate Bock and Loebell (1990), who also had consistently used he. We used have in our Non-by-locatives in order to make them as similar to passives as possible while eliminating any shared lexical content. See Table 1 for example prime stimuli.

Each priming sentence was paired with one of 32 experimental pictures. The pictures were line drawings that depicted events involving two participants, typically an inanimate or non-human agent or initiator of the action (e.g., wrecking ball) and an animate or inanimate undergoer of the action (e.g., building). Sixteen of the scenarios depicted were from the original Bock and Loebell (1990) experiment. Fourteen of the experimental pictures (44%) had the agent on the left, another fourteen (44%) had the agent on the right, and four (12%) were neutral as to the orientation of the agent relative to the undergoer on the horizontal plane (in all four, the agent was above the undergoer). All 32 experimental pictures were previously normed on Amazon Mechanical Turk (N = 195) by asking participants to write descriptions for 6–10 assorted pictures using only one sentence each, yielding a 91% median use of active or passive transitive sentences (range = 36–100%) and, among these, a 23% mean proportion of passives. (For a full list of all target pictures, see Appendix B.) Prime sentences and target pictures were randomly paired across participants. Verbs did not repeat from prime to target.

We used 42 filler sentences and 40 filler pictures. One function of these filler items was to mask the true purpose of the experiment: Participants were asked to perform a distractor memory task and indicate whether they had seen each item (sentence or picture) before or not. For this purpose, we repeated 26 of the 42 filler sentences and 28 of the 40 filler pictures, yielding a total of 68 filler sentences and 68 filler pictures. The 42 unique filler sentences instantiated a wide variety of constructions, such as clefts (e.g., It was an old lady who discovered the weapon), existentials (e.g., There is a red spot on Jupiter), resultatives (e.g., The girl laughed herself silly), dative (e.g., The singer gave the piano player a wave), generics (e.g., All humans are mammals), intransitives (e.g., The graceful young girl danced), and clausal complements (e.g., The man admitted that he was wrong). None of the filler sentences were passives. The 40 unique filler pictures depicted a variety of events involving one or more participants, typically described with intransitive sentences (e.g., boy shivering in cold, two bikes leaning on fence, girl running toward house, cat hiding behind chair, two skiers skiing). Care was taken to not select filler pictures that elicited transitive (active or passive) descriptions. In total, each participant saw 100 sentences (including the 32 primes) and 100 pictures (including the 32 targets). Filler trials were interspersed randomly between critical trials, with the constraint that the first five trials be fillers and at least one but not more than two filler trials intervene between critical trials.

2.3. Procedure

The study was administered online via Amazon Mechanical Turk using psiTurk (Gureckis et al., 2016). Participants were asked to read each sentence out loud, and to give an accurate description of each picture using the verb provided, all while recording themselves with their microphones. They were given a single opportunity to make each recording, and a microphone check preceded the task. See Fig. 2 for procedure and example materials. Participants were told not to use pronouns, to mention every depicted character, and to be as precise as possible.

For the distractor memory task, participants indicated whether they had seen each item (sentence or picture) before or not by pressing the appropriate key (left arrow for NO, right arrow for YES) on their keyboards. A post-test questionnaire confirmed that none of the participants doubted the cover story or realized the true purpose of the experiment. The whole experiment lasted approximately 45 min.

3 On average, our Non-by-locative prepositions were less frequent than by (1,293,156 vs. 2,068,768; values from the Corpus of Contemporary American English [COCA], Davies, 2008; see Appendix C), $V = 20, p = .02$ (two-tailed, one-sample Wilcoxon signed-rank test, for non-normal data). The relative infrequency of these other prepositions can be expected to increase their surprisal, which in turn predicts stronger priming effects for Non-by-locatives than By-locatives (e.g., Jaeger & Snider, 2013). Thus, if we find no priming in Non-by-locatives, it cannot be explained by these differences in frequency. We also considered how likely each preposition was given the verb (conditional probability). These values did not differ between the By-locatives and Non-by-locatives (0.04 vs. 0.06; values calculated from COCA; see Appendix C), $V = 250, p = .80$ (two-tailed, paired-sample Wilcoxon signed-rank test, for non-normal data). Thus, any differences we see in priming between the two conditions also cannot be attributed to differences in conditional probability.

2.4. Design

We used a 3 × 2 mixed design, with Prime Condition (Passive, By-locative, Non-by-locative) as a between-subjects factor and Prime Type (Non-active, Active) as a within-subjects factor. Thus, each participant saw exactly 2 conditions, 16 prime sentences of each. We manipulated Prime Condition between subjects to maximize the likelihood of observing priming in the Non-by-locative condition. This gave us ~94% power to detect priming in each condition (at a Cohen’s d of 0.28 without lexical overlap; see Mahowald et al., 2016, p. 21), and ~87% power to detect interactions between conditions (at a Cohen’s d of 0.28; see Mahowald et al., 2016, p. 21). Participants were randomly assigned to the three Prime Conditions and then to one of eight counterbalanced lists within each Prime Condition. The dependent measure was the number of passive sentences produced by participants (coded as 1, with actives coded as 0), out of all transitive responses (passive/active + passive). In presenting the production cell means (for descriptive purposes), we have aggregated over both participants and items.

2.5. Coding

The descriptions of the experimental pictures were scored for syntactic structure. If the description consisted of more than one sentence, only the first complete sentence containing both the agent and the undergoer was scored. If participants hesitated, stuttered, or produced a false start, the final form of the utterance was scored. Responses were divided into one of the three categories: Active, By-Passive, and Other.

To be scored as an Active, a target description had to provide an appropriate description of the transitive event in the target picture; had to contain the agent or initiator of the event in subject position, a verb in the active voice, and the undergoer of the event in object position; and had to be expressible in the alternative form (i.e., as a passive). To be scored as a By-Passive, a description had to be a complete sentence that appropriately described the target picture’s event; had to contain the undergoer role in subject position, an auxiliary verb (be or get), a main transitive verb, and a prepositional by-phrase with an agentic object; and had to be expressible in the alternative form (i.e., as an active). Transitive sentences with prepositional particles (e.g., crash into) were included in the analysis, so long as they could occur in both the active and the passive form. All other descriptions (including truncated, lexical, or instrumental passives; datives; intransitives; and incomplete, inaudible, or unintelligible utterances) were scored as Other. In total, 7473 of the 8770 produced target descriptions (85.2%) were transitive responses (i.e., Active or By-Passive) and thus entered into the analysis. Ten percent of the target responses were independently coded by a second coder, with an intercoder reliability of 99% (Cohen’s κ = 0.98).

2.6. Data analysis

We analyzed the data with a logistic mixed-effects model (Baayen, Davidson, & Bates, 2008; Jaeger, 2008) in the lme4 package in R (Bates, 2010), with Prime Condition (Passive, By-locative, Non-by-locative), Prime Type (Non-active, Active), and their interaction as fixed effects. We started with the maximal random effects structure appropriate for our experimental design (Barr, Levy, Scheepers, & Tily, 2013). However, this model failed to converge. The final model included random intercepts for participant and item (target picture), a random slope for Prime Type within participants, and a random slope for Prime Condition within items. All fixed effects were effect coded (1, −1). We performed forward model comparisons using likelihood-ratio tests (anova function in R) to determine the significance of our fixed effects. Table 2 summarizes the results of these comparisons. Planned pairwise analyses were run on the full model minus the relevant level of Prime Condition.

In addition, we calculated Bayes factors for the effect of priming in each condition. Unlike p-values, which only provide evidence for how unexpected the data are under the null hypothesis, Bayes factors allow us to compare the likelihood of the data fitting under the null

*Significant at the p < .05 level.
hypothesis with the likelihood of the data fitting under the alternative hypothesis. The higher a Bayes factor ($BF_{10}$), the more evidence in support of the null hypothesis; the inverse of this value thus tells us how likely the data are to occur under the alternative hypothesis ($BF_{01}$). We calculated our Bayes factors using Bayesian Information Criteria (BIC; Jarosz & Wiley, 2014; Wagenmakers, 2007). We first extracted the BIC for each hypothesis by fitting and comparing two separate regression models: one that characterizes the alternative hypothesis ($H_1$: including an effect for Prime Type, plus random intercepts for both participant and item) and one that characterizes the null hypothesis ($H_0$: same model without the effect for Prime Type). We then found the difference of these values:

$$\Delta BIC_{10} = BIC_{H_1} - BIC_{H_0}$$

Finally, we transformed this into a Bayes factor:

$$BF_{10} = e^{\Delta BIC_{10}/2}$$

And we took the inverse to quantify the odds in favor of $H_1$:

$$BF_{01} = 1/BF_{10}$$

3. Results

Accuracy on the distractor memory task was high (94%), with no differences by Prime Condition. Fig. 3 shows the pattern of priming results. The model comparisons revealed a significant main effect of Prime Type, such that passives were produced significantly more often after Non-active (Passive, By-locative, Non-by-locative) primes than after Active primes (26.0% vs. 22.0%), independent of condition, $\chi^2(1) = 45.28$, $p < .001$. However, this was in the context of a significant Prime Type by Prime Condition interaction, $\chi^2(2) = 11.41$, $p = .003$. Planned pairwise comparisons revealed that priming for Passives was significantly greater than that for Non-by-locatives (7.1% vs. −0.8%), $\beta = 0.16$ (SE = 0.04), $z = 3.51$, $p < .001$, but did not significantly differ from that for By-locatives (7.1% vs. 5.9%), $\beta = 0.04$ (SE = 0.05), $z = 0.89$, $p = .38$, and that priming for By-locatives was significantly greater than that for Non-by-locatives (5.9% vs. −0.8%), $\beta = 0.11$ (SE = 0.05), $z = 2.35$, $p = .02$. There was also a significant main effect of Prime Condition, $\chi^2(2) = 16.82$, $p < .001$. The planned pairwise comparisons revealed that significantly more passives were produced in the Passive condition as compared to either the By-locative condition (27.2% vs. 24.4%), $\beta = 0.17$ (SE = 0.09), $z = 2.00$, $p = .046$, or the Non-by-locative condition (27.2% vs. 20.4%), $\beta = 0.36$ (SE = 0.11), $z = 3.24$, $p = .001$, but the proportion of overall

$$\beta = 0.19 (SE = 0.12), z = 1.64, p = .10.$$  

Our Bayes factor analysis suggested that the data in the Passive condition were >150 times more likely to occur under a model including Prime Type (=priming) than a model without it (=no priming). The data in the By-locative condition were > 150 times more likely to occur under a model including Prime Type (=priming) than a model without it (=no priming). Lastly, the data in the Non-by-locative condition were 0.02 times more likely to occur under a model including Prime Type (=priming) than a model without it (=no priming), or in others words, ~44 times more likely to occur under a model without Prime Type (=no priming) than a model with it (=priming). Thus, by standard analysis (e.g., Jeffreys, 1961; Raftery, 1995), there is very strong or decisive evidence in support of priming in both the Passive and By-locative conditions, and conversely, strong or very strong evidence against priming in the Non-by-locative condition.

4. Discussion

We revisited a key finding in the structural priming literature that has been widely used to argue for bare constituent tree priming: that intransitive locative sentences prime passives (e.g., Bock & Loebell, 1990). We asked whether this effect was in fact due to a tendency to repeat fully abstract syntactic phrase structures, or if it might instead reflect the priming of something less abstract: an adjunct by-phrase. We have three clear findings. First, like in much past work, we replicated priming from passives to other passives, relative to active controls (see Mahowald et al., 2016). Second, we replicated Bock and Loebell (1990) finding of (equivalent) passive priming from by-locatives. Third and critically, however, we failed to find any evidence of priming from non-by-locatives to passives. Our Bayes factor analysis confirmed these interpretations. Together, these data provide strong evidence that the priming of passives by by-locatives is due, at least in part, to the presence of shared lexical content (by, be), and not to an abstract, content-less phrase structure. Notably, we also replicated Bock and Loebell (1990) finding that semantic roles do not contribute to passive priming. That is, we found no evidence that the magnitude of priming from passives to passives was greater than that from by-locatives to passives. Instead, priming in this task appears to be driven solely by the presence of the by-phrase, regardless of its semantic interpretation (agent vs. location) or the constituent structure of the clause.

One possible interpretation of the results is that the by-phrases in the prime sentences activate stored pieces of lexically-specified syntax, rather than an abstract prepositional phrase schema that can have any preposition slotted into it. This level of description is consistent with linguistic traditions that reject a strict division between syntax and the lexicon and allow for (and in fact predict) the existence of intermediate generalizations: linguistic entities that combine abstract schematic knowledge with more concrete and lexically-specified knowledge (e.g., Croft, 2001; Fillmore, 1985; Goldberg, 1995, 2006, Jackendoff, 2002, 2007; Langacker, 1987; O’Donnell, 2015; Oehrle, Bach, & Wheeler, 2012; Pollard & Sag, 1994; [CSL STYLE ERROR: reference with no printed form.]). It is alternatively possible that what’s doing all the

---

*We wanted to see whether this held for the Active primes as well as the Non-active primes. In a post-hoc analysis, we ran the same pairwise comparisons on the Active primes only (without Prime Type in the model): Although significantly more passives were produced following Active primes in the Passive condition as compared to the Non-by-locative condition (23.7% vs. 20.8%), $\beta = 0.26$ (SE = 0.13), $z = 2.06$, $p = .04$, the proportion of overall passive responses following Active primes in the By-locative condition was not significantly different from that in either the Passive condition (21.4% vs. 23.7%), $\beta = 0.18$ (SE = 0.12), $z = 1.45$, $p = .15$, or the Non-by-locative condition (21.4% vs. 20.8%), $\beta = 0.12$ (SE = 0.14), $z = 0.87$, $p = .39$.}
work is the lexical item by on its own, rather than the full prepositional phrase which it heads. One reason why we might favor the stored structure account is that prior data, using different constructions, found no evidence for the priming of function words independent of their interpretation (Bock & Loebell, 1990, Exp. 3; Ferreira, 2003). For example, Ferreira (2003) found a greater increase in that-complementation (e.g., The mechanic mentioned that the car could use a tune-up) following other that-complementation structures (e.g., The company insured that the farm was covered for two million dollars) than following a complementation structure without that (e.g., The company insured the farm was covered for two million dollars). Critically, there was no increase in that-complementation following transitive sentences with the functionally distinct deictic that (e.g., The company insured that farm for two million dollars). Likewise, Bock and Loebell (1990, Exp. 3) found no influence of infinitive to (e.g., Susan brought a book to study) on to-dative productions (e.g., The girl is handing a paintbrush to the boy). If the same processes are at work in complement priming, dative priming, and passive priming, then we should not expect by on its own to prime passives. At the same time, there are good reasons to believe that priming varies systematically across constructions depending on the representational basis of the alternation (see Ziegler, 2019; Ziegler et al., 2018). For this reason, we are reluctant to draw strong conclusions from these prior findings. Thus, it remains to be seen whether this priming is due to the by-phrase or by on its own.

In sum, the central message of the present findings is that passive priming does not result from the repetition of abstract constituent structure alone (cf. Bock & Loebell, 1990; Branigan & Pickering, 2017). In the remainder of this discussion, we situate our results in the context of the wider structural priming literature. We first discuss our assumptions about syntax (Section 4.1). We then review the evidence that has been offered in favor of content-less tree priming to determine whether it can be integrated with the present findings (Section 4.2).

4.1. A note on passive syntax

While the simplified syntactic structure in Fig. 1b led to the prediction that intransitive locatives should prime passives, in reality, there is little agreement about passive syntax. More elaborate syntactic structures have been proposed in order to represent unexpressed aspects of semantics and discourse structure. For example, an influential proposal by Baker, Johnson, and Roberts (1989) treats passive sentences as underlingly transitive (see Fig. 4). This proposal captures the idea that the subject argument of a passive corresponds to the direct object argument of an active sentence. On this theory, the distinct discourse function of the passive construction is represented by the inclusion of a passive morpheme “argument,” represented in Fig. 4 by –en, and the lack of a causer argument.

Other frameworks have treated the passive as a construction (e.g., Culicover & Jackendoff, 2005; Ginzburg & Sag, 2001) or as surface projections of individual verbs (e.g., Bresnan, 1982; Pollard & Sag, 1987). These proposals consider the passive to be syntactically intransitive, with semantics and discourse structure represented by other means. Researchers have also debated whether the by-phrase should be treated as an adjunct (e.g., Legate, 2014), an argument (e.g., Koenig, Mauner, & Bienvenue, 2003), or something in between (e.g., Grimshaw, 1990).

But importantly, no one has proposed distinct abstract tree configurations for sentences solely on the basis of the inclusion of distinct locative prepositions such as by vs. near. In order for the current set of results to be explained by syntactic priming, this assumption would be needed. Thus, the main conclusion we draw remains valid: The fact that intransitive by-locatives prime passives does not provide evidence in support of abstract syntactic priming.

4.2. Is there unambiguous evidence for the priming of abstract, content-less syntactic trees?

In addition to Bock and Loebell (1990), there are several other findings which have been argued to demonstrate that content-less phrase structure can be primed. The challenge in every case is to isolate this level of representation, given that most of the alternations we study will also vary in their lexical content, semantic event structure, information structure, and/or syntax-animacy mappings. Here we explore whether there is any priming result that must be attributed to the priming of phrase structure, with no potential confounds. We first review priming in passives, and then we branch out to other constructions.

As we can see in Table 3, the vast majority of passive priming studies are confounded by lexical content (rows 1–3), as was the case in Bock and Loebell (1990, Exp. 2). However, there are two kinds of studies where this is not the case. The first is cross-linguistic studies, in which bilingual participants are primed in one language and asked to generate target descriptions in another language (Chen, Jia, Wang, Dunlap, & Shin, 2013; Hartsuiker, Pickering, & Veltkamp, 2004; rows 4 and 5). Since the morphemes used to mark passives are distinct in the two languages, these studies appear to rule out lexicalized representations as the locus of priming. The second is a study by Messenger and Branigan (2011), in which participants were primed by short passives that did not contain an agentive by-phrase (e.g., The girls are being shocked) and produced full passives with the by-phrase (e.g., The king is being scratched by the tiger; row 6). While none of these studies allows for lexical priming (though see fn. 9), they all have at least one potential locus of priming other than content-less phrase structure (see Table 3): information structure, or the way information is "packaged" within a sentence (e.g., Lambrecht, 1994). Some evidence for structural priming comes from Vernice, Pickering, and Hartsuiker (2012), who found a tendency for Dutch-speaking participants to produce more passive sentences (e.g., De jongen wordt geraakt door de bal “The boy is hit by the ball”), which make the undergoer argument the sentence topic, following a cleft sentence with a topicalized undergoer (e.g., Degene die hij slaat is de cowboy “The one who he is hitting is the cowboy”) than one with a topicalized agent (e.g., Degene die hem slaat is de cowboy “The one who is hitting him is the cowboy”), despite differences in surface syntax (for other evidence, see, e.g., Bernolet, Hartsuiker, & Pickering, 2009; Fleischer, Pickering, & McLean, 2012; Heydell & Murray, 2000; Ziegler & Snedeker, 2019). Thus, none of the

### Discussion
Passive priming studies provide unambiguous evidence for the priming of abstract syntax (vs. lexicalized syntax, lexical content on its own, information structure, or some combination thereof).

As mentioned previously, there is reason to think that priming varies by construction depending on the representations involved (see, e.g., Ziegler, 2019; Ziegler et al., 2018). Thus, evidence that abstract, content-less trees can be primed in some cases would not provide evidence that they can be primed in all cases. Above, we reviewed passive priming and found no unambiguous evidence for the influence of abstract, content-less phrase structure. We next consider candidate evidence for abstract tree structure priming in other constructions, summarized in Table 4.7

Several of these studies (rows 1–4) build on another experiment in Bock and Loebell (1990, Exp. 1) in which motion verb sentences with locative prepositional phrases (e.g., The wealthy widow drove an old Mercedes to the church) were shown to prime to-datives (e.g., The girl is handing a paintbrush to the boy; row 1). While all of the motion verb primes and dative targets contained the preposition to in the original experiment, leaving open a lexical explanation (see also Potter & Lombardi, 1998), subsequent studies eliminated the preposition as the locus of priming (Fox Tree & Meijer, 1999, Exp. 1; Salamoura & Williams, 2007, Exp. 3; Ziegler & Snedeker, 2018, Exp. 11; rows 2–4). Nevertheless, these studies all had a common feature which suggests another possible locus of priming. Specifically, in each case, the alternative prime against which the motion verb sentences were compared was the double-object dative (e.g., Sue gave the dog a bone). Double-object datives differ from both motion verbs and to-datives in their information structure, semantic event structure, and syntax-animacy mappings. Thus, priming at any of these levels of representation could have resulted in the observed difference between the prime conditions (i.e., double-object dative primes may be pulling to-dative production down, rather than to-dative primes pulling it up).

Several other findings that manipulated the order of information in the sentence are summarized in rows 5–7. Hartsuiker et al. (1999) found that scrambled Dutch sentences in which the subject followed the verb led to more productions in which the subject followed the verb than did canonical subject-first orderings (row 5). But this type of word order difference is known to predict differences in information structure in Germanic and other languages (Hinterhölzl & Petrova, 2009; Lambrecht, 1994). Cleland and Pickering (2003) showed that relative-clause modification in English led to more relative clause productions than did prenominal attributive modification (row 6; see also Bernolet, Hartsuiker, & Pickering, 2007), but there is evidence that predicative modification (by a relative clause) differs from attributive modification, both semantically and in terms of information structure (e.g., Bolinger, 1967). Bernolet, Hartsuiker, and Pickering (2013) found priming between of-genitives in Dutch and of-genitives in English, relative to the Dutch equivalent of s-genitives (row 7), and yet here, too, there are...

* Bernolet et al. (2007) found differential priming for attributive vs. predicative constructions within English, within Dutch, and between Dutch and German, but not between Dutch and English. We know that translation-equivalents boost priming (Bernolet, Hartsuiker, & Pickering, 2012; Cai, Pickering, Yan, & Branigan, 2011; Schoonbaert, Hartsuiker, & Pickering, 2007), which would predict equivalent priming between Dutch and English as between Dutch and German. However, Bernolet et al. (2012) have found that priming across languages increases with phonological overlap in the syntactic head (in this case, the relativizer that/die/der). The greater phonological similarity between die and der could predict greater priming between Dutch and German than between Dutch and English. Therefore, consistent with the current findings, partially lexicalized translation equivalents (Rel<sub>die/der</sub> Adj V) may result in more priming than translation equivalents with less analogous morphosyntax (Rel<sub>the</sub> V Adj).
likely information structural and semantic differences since such differences exist between the analogous constructions in English (e.g., Stefanowitsch, 2003). Thus, none of these cases provides unambiguous evidence for pure tree priming.

There are two final results that are not easily attributed to lexical or information structural differences. Konopka and Bock (2009; see also Gries, 2005) have found priming of verb-particle placement in English: Participants produced more verb-particle constructions with the direct object intervening (e.g., *The high prices scared the customers off*) following configurations with the same ordering (e.g., *The burglars broke the door down*) than configurations in which the particle occurred right after the verb and before the direct object (e.g., *The burglars broke down the door*; row 8). The ordering of the particle and direct object is conditioned by various semantic and information structural factors (Gries, 1999), but the priming effect was found even when these factors were controlled for (Konopka & Bock, 2009) or taken into account (Gries, 2005).

Another intriguing finding comes from Hartsuiker and Westenberg (2000), who found priming of auxiliary placement in Dutch: Participants were more likely to place the finite auxiliary verb in a subordinate clause before the participle (e.g., *had gebroken*) following a prime with the same order (e.g., *was geblokkeerd*) than after a prime with verb-final ordering (e.g., *geblokkeerd was*; row 9), regardless of whether responses were verbal or written. While differences in constituent ordering commonly reflect differences in information structure, as noted above, information structure does not appear to condition this difference (for discussion, see Hartsuiker & Westenberg, 2000; Pappert & Pechmann, 2014). Instead, the variation is conditioned by dialect, choice of auxiliary, and prosody (rhythm; De Sutter, 2009; Swerts & van Wijk, 2005). Intriguingly, the ordering of direct object and verb-particle—which also shows somewhat mysterious priming effects—has rhythmic correlates as well (Déhé, 2002). The possibility of rhythmic priming in language has not been widely studied, and the evidence that does exist is mixed: While no evidence has been found for priming of pauses within sentences (Tooley, Konopka, & Watson, 2014, 2018), and one study found no evidence of lexical stress priming (Bock & Loebell, 1990, Exp. 3), other work that used tone sequences found rhythmic priming for word lists (Cason & Schön, 2012) and for sentences with matching rhythmic structure (Cason, Astésano, & Schön, 2015). Clearly, more work is needed to determine whether (explicit or implicit) rhythmic structure, or any of the other factors besides syntax in Table 4, is responsible for the priming in each case.

5. Conclusion

Priming is a powerful tool for studying linguistic representation (e.g., Branigan & Pickering, 2017). In this paper, we questioned a key argument underlying claims that structural priming is based on tree structures devoid of meaning and morphology. In particular, we asked whether the priming Bock and Loebell (1990) observed between intransitive-by-locatives and passives was driven by an abstract syntactic phrase structure, as has commonly been assumed (e.g., Bock & Griffin, 2000; Branigan & Pickering, 2017; Branigan et al., 1995; Chang et al., 2006; Pickering & Branigan, 1998; Pickering, Branigan, & McLean, 2002; Pickering & Ferreira, 2008; Rowland, Chang, Ambridge, Pine, & Lieven, 2012). We found that priming did not occur when the locatives did not contain the preposition *by*. This forces us to reexamine the priming literature. In doing so, we observe that the loci of structural priming vary across constructions in ways which correspond to our theories of the representational bases of the alternations involved. These data highlight the importance of revisiting old conclusions with attention to the full range of factors that may be relevant for the selection of various types of grammatical patterns or constructions (for discussion, see Ziegler, Snedeker, & Wittenberg, 2017).
